## **Set 22: Styling DOM Elements**

```
Skill 22.01: Review how to select DOM elements
Skill 22.02: Write code to style text
Skill 22.03: Write code to style block elements
Skill 22.04: Write code to position elements
```

## Skill 22.01: Review how to select DOM elements

## Skill 22.01 Concepts

Before we dive in to writing code to style DOM elements, let's first revisit how we can select DOM elements.

Notice in the above example, that at the root of our model is the *document* object. In JavaScript, the *document* object is the door to the DOM structure. Before you can access a specific element within the document you must first access this root object. Consider the following code which logs the document object to the console. Within the document you can see the entire contents of the webpage.

Code	Output
<pre>console.log(document);</pre>	▼#document
	html
	<html></html>
	▶ <head></head>
	▶ <body></body>

The elements within the document of the page can be selected using the dot notation. Below are some examples,

Code	Output
<pre>console.log(document.head);</pre>	▼ <head></head>
<pre>console.log(document.body);</pre>	<pre>▼ <body></body></pre>
<pre>console.log(document.title);</pre>	Davie JR's Menu

In addition to selecting elements by their name, we can also select elements by their id. Consider the output for the following code snippets which reference the HTML page below,

```
Code
                                                      Output
                                                       ▼<div id="nav">
console.log(document.getElementById("nav"));
                                                         <img id="logoImage" src="Images/logo.svg">
                                                         <a href="#menu">MENU</a>
                                                         <a href="#nutrition">NUTRITION</a>
                                                         <a href="#order">ORDER</a>
                                                         <a href="#locations">LOCATIONS</a>
                                                        </div>
console.log(document.getElementById("content"));
                                                        ▼<div id="content">
                                                         ▶ <div id="menu">...</div>
                                                         ▶ <div id="nutrition">...</div>
                                                         </div>
<!DOCTYPE html>
<html>
  <head>
   <script src="App.js" defer></script>
   <title>Davie JR's Menu</title>
  </head>
  <body>
    <img id = "foodLogoImage" src="Images/foodlogo.png">
    <div id="description"></div>
    <div id = "nav">
      <img id = "logoImage" src="Images/logo.svg">
      <a href="#menu">MENU</a>
      <a href="#nutrition">NUTRITION</a>
      <a href="#order">ORDER</a>
      <a href="#locations">LOCATIONS</a>
    </div>
    <div id="content">
      <div id="menu">
          <img id = "burgerImage" src = "Images/burger.jpg">
          <h1>BBQ BACON BURGER</h1>
          BBQ Bacon Burger
          <a href="#" id="button">ORDER NOW</a>
      </div>
      <div id="nutrition">
          CALORIES
          678
      </div>
    </div>
</body>
</html>
```

## Skill 22.01 Exercise 1

#### Skill 22.02 Concepts

Previously, we learned how to assign and change the text of an element using the .innerHTML property.

For example, the following code reassigns the inner HTML of the body element to the text 'The cat loves the dog':

```
document.body.innerHTML = "The cat hates the dog";
```

The .innerHTML property can also add any valid HTML, including properly formatted elements. The following example assigns an h2 element inside the <body> element:

```
document.body.innerHTML = '<h2>This is a heading</h2>';
```

Below are more examples,

```
Code
                                                         Output
var someText = "Yummy!";
                                                          <div id="description">Yummy!</div>
document.getElementById("description").innerHTML =
someText;
console.log(document.getElementById("description"));
var someText = "Not available";
                                                         <a href="#" id="button">Not available</a>
document.getElementById("button").innerHTML =
someText;
console.log(document.getElementById("button"));
<!DOCTYPE html>
<html>
  <head>
   <script src="App.js" defer></script>
   <title>Davie JR's Menu</title>
  </head>
  <body>
    <img id = "foodLogoImage" src="Images/foodlogo.png">
    <div id="description"></div>
    <div id = "nav">
      <img id = "logoImage" src="Images/logo.svg">
      <a href="#menu">MENU</a>
      <a href="#nutrition">NUTRITION</a>
      <a href="#order">ORDER</a>
      <a href="#locations">LOCATIONS</a>
    </div>
    <div id="content">
      <div id="menu">
         <img id = "burgerImage" src = "Images/burger.jpg">
         <h1>BBQ BACON BURGER</h1>
         BBQ Bacon Burger
         <a href="#" id="button">ORDER NOW</a>
      </div>
```

It is also possible to change how the text looks by modifying the *style* property of the element in which the text is displayed. The *.style* property of a DOM element provides access to the inline style of that HTML tag.

#### **Font Color**

To change the color of text we first indicate the *style* property, followed by the *.color* property. This is illustrated in the following example. Notice that we simply typed the color "red" and the browser new how to interpret it. Modern browsers support 140 named colors, which are listed here, <a href="https://htmlcolorcodes.com/color-names">https://htmlcolorcodes.com/color-names</a>

### **Font Size**

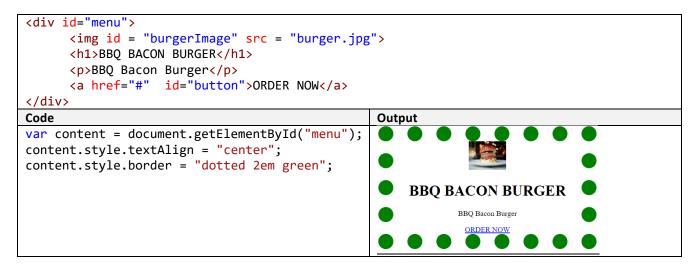

The size of font can be specified with the *.fontSize* property. Because different screens render text differently, it is best practices to specify the font size relative to the screen on which it is to be displayed. This is done using *em* units. For example, if you specify the *fontSize* to 2 em, the font will appear 2x as large. If you specify the *fontSize* to 1.5 em, the font will appear 1.5x as large, etc.

#### Font Style

There are three basic font styles you can apply to text: normal, italic, or oblique. These can be applied with the .fontStyle property.

## **Text Alignment**

The text within an element can be aligned as left, right, or center using the .textAlign property.

## Skill 22.02 Exercise 1

## Skill 22.03 Write code to style block elements

## Skill 22.03 Concepts

A block element is an element that takes up space on a web page. Below lists the basic characteristics of a block element,

- A block-level element always starts on a new line.
- A block-level element always takes up the full width available (stretches out to the left and right as far as it can).
- A block level element has a top and a bottom margin, whereas an inline element does not.

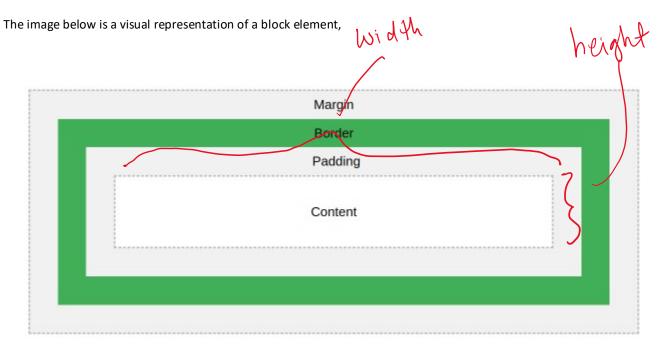

All block elements have the following properties which can be defined using the elements style property.

Width and height — specifies the width and height of the content area.

**Padding** — specifies the amount of space between the content area and the border.

**Border** — specifies the thickness and style of the border surrounding the content area and padding.

**Margin** — specifies the amount of space between the border and the outside edge of the element.

We have already encountered many block elements. Below are some examples,

Index.html	App.js
<h1 id="h1-head">This is an H1</h1>	<pre>var h1 = document.getElementById("h1-head");</pre>
header	<pre>h1.style.backgroundColor = "yellow";</pre>
<h2 id="h2-head">This is an H2</h2>	<pre>var h2 = document.getElementById("h2-head");</pre>
header	h2.style.backgroundColor = "purple";
<pre>This is a paragraph</pre>	<pre>var p = document.getElementById("para");</pre>
	<pre>p.style.backgroundColor = "green";</pre>

# This is an H1 header

## This is an H2 header

This is a paragraph

Another block element commonly used to organize content is the <div></div> tag. And, just as the tag implies, the <div> tag is used to *divide* content.

Index.html	App.js
<div id="div1">This is a</div>	<pre>var div1 = document.getElementById("div1");</pre>
divider	<pre>div1.style.backgroundColor = "yellow";</pre>
<div id="div2">This is another</div>	<pre>var div2 = document.getElementById("div2");</pre>
divider	<pre>div2.style.backgroundColor = "purple";</pre>
<div id="div3">This is yet another</div>	<pre>var div3 = document.getElementById("div3");</pre>
divider	<pre>div3.style.backgroundColor = "green";</pre>
	Output
This is a divider	
This is another divider	
This is a yet another divider	

The above examples illustrate how to use the *backgroundColor* property to style the background of a block element. Below are examples of how we can style other properties associated with block elements.

```
Index.html
                                            App.js
<div id="div1">This is a divider</div>
                                            var div1 =
                                            document.getElementById("div1");
                                            div1.style.backgroundColor = "yellow";
                                            div1.style.width = "50%";
                                            div1.style.height = "500px";
                                            div1.style.padding = "2em";
                                            div1.style.borderWidth = "2em";
                                            div1.style.borderStyle = "dotted";
                                            div1.style.borderColor = "blue";
                                            div1.style.borderRadius = "20%";
                                            div1.style.margin = "2em";
                                         Output
      This is a divider
```

Property	Description	Example
backgroundColor	The background color of the element	<pre>var div1 = document.getElementById("div1"); div1.style.backgroundColor = "yellow";</pre>
width	Specifies the width of the element	<pre>div1.style.width = "50%";</pre>
height	Specifies the height of the element	<pre>div1.style.height = "500px";</pre>
padding	Specifies the amount of space between the content area and the border	<pre>div1.style.padding = "2em";</pre>
margin	specifies the amount of space between the border and the outside edge of the element.	<pre>div1.style.margin = "2em";</pre>
borderWidth	Specifies the thickness of a border	<pre>div1.style.borderWidth = "2em";</pre>
borderColor	Specifies the color a border	<pre>div1.style.borderColor = "blue";</pre>
borderStyle	Specifies the type of border: dotted, dashed, double, solid, etc*	<pre>div1.style.borderStyle = "dotted";</pre>
borderRadius	Specifies the curvature of the the border	<pre>div1.style.borderRadius = "20%";</pre>
*For more border	styles, check this out	: https://www.w3schools.com/css/css_border.asp

Notice in units used in the above examples: em, px, and %. The units you choose depends on your use case. Below is a description of each unit,

Unit	Description
em	Relative to the font-size of the element (2em means 2 times the size of the current font)
рх	A fixed size. pixels (1px = 1/96th of 1in)
%	Relative to the parent element

## Skill 22.03 Exercises 1

## Skill 22.04 Concepts

The default position for all block elements is the far-left side of the screen. And, unless specified otherwise, they take up the full width of the page. Notice in the example below, each block element is positioned to the far-left and they are displayed vertically relative to one another.

```
Index.html
                                        App.js
<div id = "one"></div>
                                        var one = document.getElementById("one");
<div id = "two"></div>
                                        var two = document.getElementById("two");
<div id = "three"></div>
                                        var three = document.getElementById("three");
                                        one.style.height = "5em";
                                        two.style.height = "5em";
                                        three.style.height = "5em";
                                        one.style.width = "50%";
                                        two.style.width = "50%";
                                        three.style.width = "50%";
                                        one.style.backgroundColor = "yellow";
                                        two.style.backgroundColor = "purple";
                                        three.style.backgroundColor = "gray";
                                          Output
```

The default position of an element can be changed by setting its *position* property. The *position* property can take one of four values:

- 1. static- the default value (it does not need to be specified)
- 2. relative
- 3. absolute
- 4. fixed

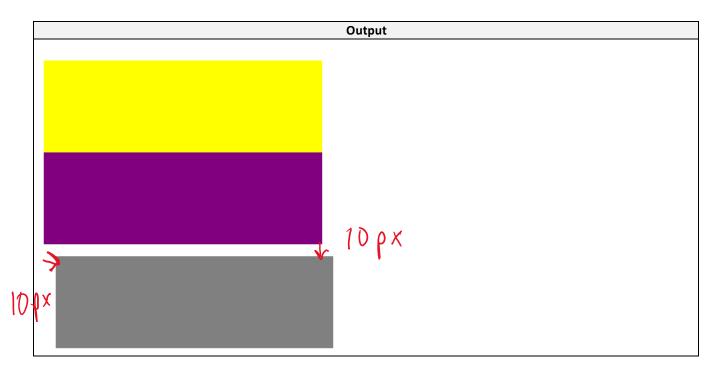

Each type of positioning is described in more detail below.

## Relative positioning

The *relative* value allows you to position an element *relative* to its default position on the web page.

In the example below, div three is shifted 10px from the top and left border relative to its default location.

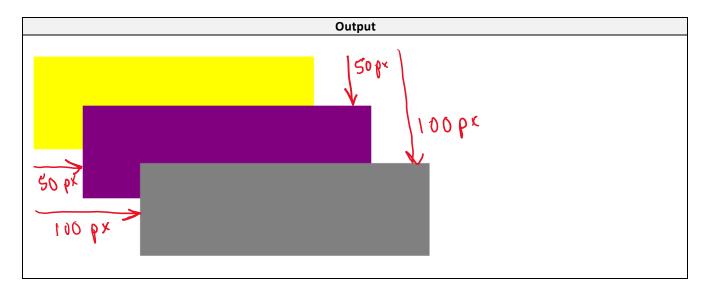

```
Index.html
                                        App.js
<div id = "one"></div>
                                        var one = document.getElementById("one");
<div id = "two"></div>
                                        var two = document.getElementById("two");
<div id = "three"></div>
                                        var three = document.getElementById("three");
                                        one.style.height = "5em";
                                        two.style.height = "5em";
                                        three.style.height = "5em";
                                        one.style.width = "50%";
                                        two.style.width = "50%";
                                        three.style.width = "50%";
                                        one.style.backgroundColor = "yellow";
                                        two.style.backgroundColor = "purple";
                                        three.style.backgroundColor = "gray";
                                        three.style.position = "relative";
                                        three.style.top = "10px";
                                        three.style.left = "10px";
```

## Absolute positioning

When an element's position is set to *absolute* you can place the element exactly where you want relative to the page. All elements on the page will ignore an element that is positioned with the *absolute* designation.

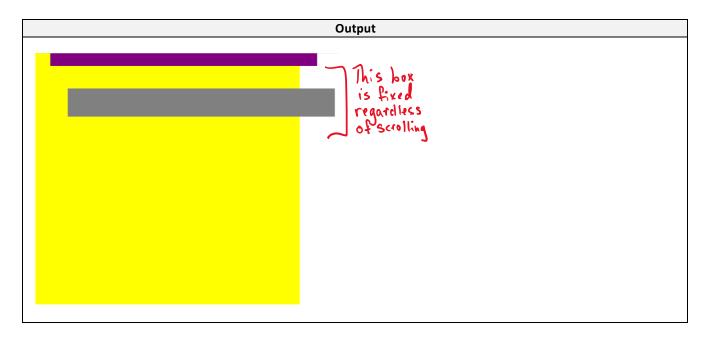

```
Index.html
<div id = "one"></div>
                                        var one = document.getElementById("one");
<div id = "two"></div>
                                        var two = document.getElementById("two");
<div id = "three"></div>
                                        var three = document.getElementById("three");
                                        one.style.height = "5em";
                                        two.style.height = "5em";
                                        three.style.height = "5em";
                                        one.style.width = "50%";
                                        two.style.width = "50%";
                                        three.style.width = "50%";
                                        one.style.backgroundColor = "yellow";
                                        two.style.backgroundColor = "purple";
                                        three.style.backgroundColor = "gray";
                                        two.style.position = "absolute";
                                        two.style.top = "50px";
                                        two.style.left = "50px";
                                        three.style.position = "absolute";
                                        three.style.top = "100px";
                                        three.style.left = "100px";
```

## Fixed positioning

We can fix an element to a specific position on the page (regardless of user scrolling) by setting its position to fixed.

```
Index.html
                                         App.js
<div id = "one"></div>
<div id = "two"></div>
                                         var one = document.getElementById("one");
                                         var two = document.getElementById("two");
<div id = "three"></div>
                                         var three = document.getElementById("three");
                                         one.style.height = "50em";
                                         two.style.height = "5em";
                                         three.style.height = "5em";
                                         one.style.width = "50%";
                                         two.style.width = "50%";
                                         three.style.width = "50%";
                                         one.style.backgroundColor = "yellow";
                                         two.style.backgroundColor = "purple";
                                         three.style.backgroundColor = "gray";
                                         two.style.position = "absolute";
                                         two.style.top = "50px";
                                         two.style.left = "50px";
                                         three.style.position = "fixed";
                                         three.style.top = "100px";
                                         three.style.left = "100px";
```
